Abstract

Lung disease and elevation of blood glucose are associated with increased glucose concentration in the airway surface liquid (ASL). Raised ASL glucose is associated with increased susceptibility to infection by respiratory pathogens including *Staphylococcus aureus* and *Pseudomonas aeruginosa*. We have previously shown that the anti-diabetes drug, metformin, reduces glucose-induced *S. aureus* growth across *in vitro* airway epithelial cultures. The aim of this study was to investigate whether metformin has the potential to reduce glucose-induced *P. aeruginosa* infections across airway epithelial (Calu-3) cultures by limiting glucose permeability. We also explored the effect of *P. aeruginosa* and metformin on airway epithelial barrier function by investigating changes in tight junction protein abundance. Apical *P. aeruginosa* growth increased with basolateral glucose concentration, reduced transepithelial electrical resistance (TEER) and increased paracellular glucose flux. Metformin pre-treatment of the epithelium inhibited the glucose-induced growth of *P. aeruginosa*, increased TEER and decreased glucose flux. Similar effects on bacterial growth and TEER were observed with the AMP activated protein kinase agonist, 5-aminoimidazole-4-carboxamide ribonucleotide. Interestingly, metformin was able to prevent the *P. aeruginosa*-induced reduction in the abundance of tight junction proteins, claudin-1 and occludin. Our study highlights the potential of metformin to reduce hyperglycaemia-induced *P. aeruginosa* growth through airway epithelial tight junction modulation, and that claudin-1 and occludin could be important targets to regulate glucose permeability across airway epithelia and suppress bacterial growth. Further investigation into the mechanisms regulating metformin and *P. aeruginosa* action on airway epithelial tight junctions could yield new therapeutic targets to prevent/suppress hyperglycaemia-induced respiratory infections, avoiding the use of antibiotics.

Introduction

The airway epithelium is covered by a thin layer of surface liquid (ASL), which is vital for maintaining a healthy respiratory tract. The ASL contains many potential growth substrates for bacterial growth including glucose. Glucose concentration in human ASL is normally ~0.4 mM, 12.5 times lower than that of blood [1]. Airway surface liquid glucose concentrations are elevated in individuals with respiratory disease including acute viral rhinitis [2], chronic rhinosinusitis [3], chronic obstructive pulmonary disease [4] and cystic fibrosis [1]. Airway surface liquid glucose concentrations are also increased in experimental and diabetic hyperglycaemia [2, 5] and are further increased in individuals with both respiratory disease and diabetes mellitus [1, 6]. Such elevations in ASL glucose are associated with increased susceptibility to infection, particularly with *S. aureus* and *Pseudomonas aeruginosa* [4, 6, 7].

We developed an *in vitro* model of airway glucose homeostasis and showed that ASL glucose concentration is the net effect of the paracellular diffusion of glucose from the blood/interstitial fluid across the airway epithelium into ASL and its removal from ASL by epithelial uptake through facilitative glucose transporters [8–11]. We showed that paracellular glucose diffusion was increased not only by...
elevating basolateral glucose concentrations (mimicking hyperglycaemia of blood/interstitial fluid), but also by inflammation. In human epithelial cell monolayers, we found that application of either apical pro-inflammatory cytokines [9] or apical bacterial pathogens [12, 13] increased paracellular glucose flux, increasing glucose concentrations in ASL. Under pro-inflammatory conditions, airway epithelial glucose uptake through apical GLUTs is elevated, but this is insufficient to compensate for the increased paracellular glucose leak and does not prevent elevation of ASL glucose concentrations [9]. Control of paracellular glucose movement thus appears to be the main rate-limiting step for maintaining low ASL glucose concentrations.

We have previously shown that pre-treatment of airway epithelial monolayers with the anti-diabetes drug, metformin, attenuated the effects of S. aureus on paracellular glucose flux and reduced bacterial growth in ASL by restricting glucose availability [12]. Reducing glucose permeability could therefore be a therapeutic target in the prevention and treatment of respiratory S. aureus infections.

Epithelial barrier dysfunction during bacterial infections is characterized by alterations in tight junction protein abundance. Tight junctions, the most apically located of the intercellular junctional complexes, regulate the passage of fluid, ions, macromolecules and inflammatory cells through the paracellular space between epithelial cells. Tight junctions are formed by three classes of integral membrane proteins: claudins, occludins and junctional adhesion molecules. Directly underneath tight junctions, are another specialized cell–cell contact domain, adherens junctions, which are mainly composed of cadherin family members. The composition of these protein complexes regulates epithelial permeability to solutes and ions. Factors that alter the abundance and localization of specific tight junction proteins within this complex could therefore alter glucose permeability.

The aim of this study was to determine whether metformin also has the potential to reduce glucose-induced P. aeruginosa infections across airway epithelial cultures by limiting glucose permeability. We used the adenocarcinoma cell line, Calu-3, derived from human tracheobronchial submucosal glands, which form a heterogeneous population of mucus (mucin-secreting) and serous (fluid-secreting) cell types [14, 15]. Calu-3 cells secrete a fluid rich in antimicrobial secretions to suppress bacterial growth [16] and form polarized airway epithelial monolayers with functional tight junctions expressing many of the integral membrane proteins found in vivo [17, 18]. We explored the effect of P. aeruginosa and metformin on airway epithelial barrier function by investigating changes in tight junction protein abundance.

Materials and methods

Airway epithelial cell culture

The human adenocarcinoma-derived cell line, Calu-3 (from ATCC), was grown in Eagle’s minimal essential medium plus 10% fetal calf serum, 2 mM L-Glutamine, 100 units/ml penicillin, 100 μg/ml streptomycin, and 1% non-essential amino acids (Sigma-Aldrich, Poole, UK) and incubated in humidified air containing 5% CO2 at 37°C. Calu-3 cells were seeded onto clear Costar Transwell inserts (0.45-μm pore size) at 250,000 cells/cm² to form confluent polarized monolayers, as previously described [19]. Experiments were carried out 10–14 days post-seeding. Twenty-four hours before the experiment, monolayers were washed to remove the mucus layer and placed in Krebs salt solution consisting of 115 mM NaCl, 5 mM KCl, 25 mM NaHCO3, 1 mM MgCl2, 1 mM CaCl2 and 5 mM D-glucose (equilibrated with 5% CO2 to pH 7.4) to remove antibiotics and components of the media that could influence bacterial growth.

Calu-3 monolayers were pre-treated with (or without) metformin (0.02 or 1 mM) or 5-aminomimidazole-4-carboxamide ribonucleotide (AICAR; 0.5 mM), added to the basolateral medium 18 hrs prior to apical inoculation with P. aeruginosa. Metformin was applied to the basolateral membrane to mimic the situation in vivo, in which metformin would reach the airway epithelium via the blood/interstitial fluid. Calu-3 cells and other bronchial cell types express organic cation transporter 3 on the basolateral membrane which is known to facilitate metformin uptake [20–22].

Using a chopstick style epithelial voltohmmeter (WPI, Hitchin, UK), Transepithelial electrical resistance (TEER) measurements were made, a widely accepted quantitative technique to measure the presence of tight junctions, the major component of epithelial cell barrier integrity in cell culture models of epithelial monolayers. Transepithelial electrical resistance measurements quantify the transport of ions across the cells with paracellular ion transport representing the most substantial contribution to such readings. An intact cellular barrier displays high TEER values. Loss of barrier integrity leads to decreased TEER values.

Airway epithelia – P. aeruginosa co-culture

A single colony of P. aeruginosa strain PA01 was incubated overnight at 37°C in RPMI media (Life Technologies, Paisley, UK) and diluted with glucose-free RPMI to produce a culture of approximately 107 colony forming units (CFU) per ml. 100 μl of PA01 culture (1 × 105 CFU total) was applied to the apical surface of Calu-3 monolayers. Co-cultures were bathed in Krebs salt solution. Normal blood glucose or hyperglycaemia was modelled by applying basolateral glucose concentrations of 5 and 15 mM respectively. Co-cultures were placed in a CO2 incubator at 37°C for 7 hrs, after which either cell lysates were collected for Western blotting or cells were homogenized and CFU calculated by plating out serial dilutions. Bacterial growth was external in the ASL, with minimal epithelial invasion observed after 7 hrs.

Paracellular L-glucose flux experiments

Paracellular movement of glucose across Calu-3 monolayers was measured by analysis of radiolabelled [14C]-L-glucose transepithelial flux. Experiments were initiated by adding 1 ml of Krebs salt solution containing 1.0 μCi of [14C]-L-glucose plus 10 mM of non-radiolabelled equivalent glucose to the basolateral side of the transwells and 0.1 ml of glucose-free Krebs salt solution to the apical side. Apical and basolateral samples were taken after 1 hr and the concentration of radiolabelled glucose was analysed using a scintillation counter.

Western blotting for tight junction proteins

After cells were co-cultured they were lysed in ERK Phosphorylated buffer containing 20 mM Tris-HCL pH 7.5, 150 mM NaCl, 1 mM

ethylenediaminetetraacetic acid, 50 mM NaF, 1 mM NaVO₄, 1% w/v Triton-X, 0.5% w/v sodium deoxycholate, 0.1% w/v SDS, 1 µg/ml protease inhibitor cocktail (P8340; Sigma-Aldrich). Cells were sonicated and cell debris was removed by centrifugation at 10,000 × g at 4°C for 10 min. Total protein concentration was determined by Bradford Assay and between 30 and 60 µg was electrophoresed on NuPage Novex 10% Bis-Tris Protein Gels (Invitrogen, Paisley, UK). Protein was then transferred for 70 min. onto polyvinylidene difluoride membranes (Merck Millipore, Watford, UK). Non-specific reactivity was blocked in Odyssey Blocking Buffer diluted 1:1 in PBS for 1 hr at room temperature. Blots were incubated overnight with the following antibodies obtained from Life Technologies and used at 1:500 dilution; mouse anti-E-Cadherin (33-4000), rabbit anti-Claudin-1 (51-9000) and rabbit anti-Occludin (H-279; Santa Cruz Biotechnology, Heidelberg, Germany). The blots were then washed in Tris-buffered saline/0.2% Tween 20 and incubated with either Donkey antimouse IgG (926-3221; LI-COR Biosciences, Cambridge, UK) or goat anti-rabbit IgG (LI-COR Biosciences) for 1 hr at room temperature and kept in the dark. Blots were subsequently probed with a mouse monoclonal antibody to β-actin. Detection of antigen–antibody complexes was assessed using a Licor Odyssey Western blot imaging system. Integrated density of each fluorescent band was determined using Image Studio Lite Ver 3.1 (Licor). Results are expressed as a ratio to β-actin control within the same sample.

Chemicals and reagents

All chemical and reagents were obtained from Sigma-Aldrich unless otherwise stated.

Statistical analysis

Values are reported as mean ± S.E.M. Statistical analysis was performed with ANOVA and post hoc Tukey’s or Student’s t-test. P-values <0.05 were considered significant.

Results

Metformin- and AMP-activated protein kinase agonist AICAR restrict glucose-induced P. aeruginosa growth in airway epithelial-bacteria co-cultures

Elevating basolateral glucose from 5 to 15 mM in Calu-3 airway epithelial co-cultures increased apical P. aeruginosa growth by 66 ± 12% (P < 0.01; n = 5; Fig. 1A). Pre-treatment of the epithelium with 1 mM metformin (18 hrs) significantly reduced apical P. aeruginosa growth in the presence of normoglycemic (5 mM) and hyperglycaemic (15 mM) basolateral glucose concentrations (P < 0.05; n = 5). A significant reduction in hyperglycaemic-induced P. aeruginosa growth was also observed using clinically relevant concentrations of metformin (Fig. 1B; 20 µM metformin; usual metformin dose is approximately 15–30 mg/kg/day, producing plasma concentrations ~5–20 µM) [23, 24].

It is well documented that metformin activates AMP-activated protein kinase (AMPK) [25], which is known to play an important role in tight junction assembly [26]. In addition the AMPK agonist, AICAR has previously been shown to partially prevent tight junction disassembly (induced by calcium depletion) [27]. We therefore tested the effect of epithelium pre-treatment with AICAR (0.5 mM, 18 hrs) and found that this also reduced P. aeruginosa growth by 52 ± 9% under hyperglycaemic conditions (P < 0.05; n = 6; Fig. 1B).

Metformin attenuates the effects of P. aeruginosa on Calu-3 TEER and transepithelial glucose flux

Pre-treatment with 1 mM metformin increased Calu-3 monolayer TEER from 676 ± 33 to 756 ± 54 Ω/cm² (P < 0.05; n = 5; Fig. 2A). The addition of P. aeruginosa to the apical surface produced a significant decrease in TEER to 477 ± 21 Ω/cm² after 6 hrs of co-culture (P < 0.01; n = 5; Fig. 2A). Metformin treatment (both 1 mM and 20 µM) attenuated the fall in TEER produced by apical P. aeruginosa (P < 0.05; n = 5–6), which was prevented by pre-treatment with the AMPK inhibitor compound C (Fig. 2B). AICAR pre-treatment also attenuated the P. aeruginosa-induced reduction in Calu-3 TEER (P < 0.05; n = 6; Fig. 2B).

The decrease in TEER evoked by apical P. aeruginosa induced an increase in the rate of basolateral-to-apical paracellular glucose flux by 47.6 ± 5.8% (P < 0.01, n = 4; Fig. 2C), which could be partially overcome following metformin treatment (P < 0.05; n = 4). Metformin had no significant effect on paracellular glucose flux in the absence of P. aeruginosa (P > 0.05; n = 4; Fig. 2C), despite increasing Calu-3 TEER, consistent with the non-linear relationship between TEER and paracellular glucose permeability (large changes in TEER are required at high TEER to induce small changes in paracellular flux; conversely small changes in TEER at low TEER produce relatively large changes in paracellular flux) [8].

Metformin increases claudin-1 and occludin protein abundance to prevent P. aeruginosa-induced tight junction disruption

We investigated the effects of P. aeruginosa and metformin on the abundance of tight junction (claudin-1 and occludin) and adherens junction (E-cadherin) proteins.

Claudin-1 protein abundance was elevated by 16 ± 8% after 18 hrs in the presence of 1 mM metformin (P < 0.05; n = 4; Fig. 3A). Co-culture with P. aeruginosa produced a small decline in claudin-1 abundance (P < 0.05; n = 4), although this could be overcome by metformin pre-treatment (P < 0.01; n = 4).

Metformin pre-treated Calu-3 cells exhibited significantly increased occludin abundance by 38 ± 9% compared to the untreated controls (P < 0.01; n = 7; Fig. 3B). Pseudomonas aeruginosa addition resulted in reduced abundance of occludin (65 kDa band), as well as the appearance of occludin cleavage fragments.
consistent with previous studies of \( P. \) \textit{aeruginosa}\)-induced changes in airway epithelia tight junctions [28]. Interestingly, the abundance of \( P. \) \textit{aeruginosa}\)-induced occludin cleavage fragments (~45 kD and ~35 kD) was significantly reduced by metformin pre-treatment (by 34 ± 7% and 18 ± 5%, respectively; \( P < 0.05; n = 4 \)).

E-cadherin abundance was not significantly altered by either metformin or \( P. \) \textit{aeruginosa}\) addition (\( P > 0.05; n = 3 \); Fig. 3C).

Discussion

Our study highlights the potential of metformin to reduce hyperglycaemia-induced \( P. \) \textit{aeruginosa}\) growth through modulation of airway epithelial tight junctions. Metformin pre-treatment of Calu-3 airway epithelial cells reduced hyperglycaemia-induced apical \( P. \) \textit{aeruginosa}\) growth consistent with our previous observations where metformin decreased hyperglycaemia-induced apical \( S. \) \textit{aureus} growth on H441 and primary human bronchial epithelial cells (HBEC) [12]. A similar attenuation of \( P. \) \textit{aeruginosa}\)-induced changes in TEER and restricted bacterial growth were observed with the AMPK agonist, AICAR and metformin failed to significantly alter the bacteria-induced reduction in TEER in the presence of the AMPK inhibitor, compound C. These data therefore indicate a potential AMPK-dependence in metformin’s ability to prevent \( P. \) \textit{aeruginosa}\)-induced impairment of airway epithelial barrier function.
Metformin increased occludin and claudin-1 abundance which correlated with increased TEER and reduced paracellular glucose flux across Calu-3 cells. The route by which glucose crosses airway epithelial tight junctions has not been defined. We have shown that, although glucose permeability is related to TEER which is a measurement of ionic permeability it is not a direct linear relationship [8]. Moreover, permeability of ions can be restricted by the presence of specific tight junction proteins which influence charge selectivity of the tight junction [29]. Thus, the alterations in tight junction composition that determine glucose permeability as a larger non-ionic solute are likely to be different to that of ions. Exploring the tight junction proteins modified by metformin to reduce glucose permeability in the presence of bacteria may highlight key proteins involved in regulating paracellular glucose movement.

*Pseudomonas aeruginosa* addition reduced the abundance of full-length occludin (~65 kD) and produced occludin-cleavage products consistent with previous reports [28]. Furthermore, we showed that this was associated with increased glucose permeability confirming previous findings that reduced abundance of occludin increased the permeability of epithelial cells to ethanolamine and mannitol, non-charged solutes of similar size to glucose [30].

Cleavage of occludin was shown to occur via TLR-2-dependent activation of calpains in airway epithelial cell monolayers co-cultured with *P. aeruginosa* strain PA01 [28]. The abundance of cleaved occludin proteins was significantly reduced by metformin, suggesting that metformin may inhibit this pathway. Metformin is known to have anti-inflammatory effects in airway epithelial cells [31] and in a study of 30 diabetic patients, those on metformin therapy exhibited lower blood TLR-2 expression [32]. Calpains are Ca\(^{2+}\)-dependent proteases that are ubiquitously expressed in cells and tissues. Knockdown of calpains 1 and 2 reduced cleavage of occludin in epithelial cells [28].

Currently, there is no evidence for any effect of metformin on calpain activity in airway cells although metformin treatment efficacy in patients has been linked with polymorphisms in the gene for calpain-10 [33].

Claudin-1 abundance was also reduced in the presence of *P. aeruginosa*, which has similarly been shown to be regulated by TLR2-dependent signalling pathways in Calu-3 cells [34]. Claudin-1 is expressed ubiquitously in most epithelial tissues of the body [35], including the airway epithelium and to a lesser extent the alveolar epithelium [36, 37]. *In vitro* studies have shown that claudin-1 acts predominantly as a barrier-forming tight junction protein, with overexpression leading to an increase in TEER [38, 39]. Knockout of claudin-1 in mice leads to loss of the tight junctional barrier to water and macromolecules across the epidermis [40]. Consistent with our findings, downregulation of claudin-1 increased paracellular permeability to non-charged molecules in airway epithelial cells [41].

Interestingly, TLR2 agonists were able to modify claudin-1 expression through atypical PKC \(\zeta\) [34], which is a known target of AMPK in alveolar epithelial cells [42]. Given that metformin is an AMPK agonist, and similar effects on TEER and bacterial growth were produced by the AMPK agonist AICAR, it is possible that claudin-1 expression is regulated by metformin through AMPK-dependent phosphorylation of PKC \(\zeta\).

The changes in abundance shown in this study highlight potential roles for claudin-1 and occludin in the action of metformin to prevent the *P. aeruginosa*-induced increase in glucose permeability and hyperglycaemia-induced growth. Although metformin treatment is likely to affect other tight junction proteins, both claudin-1 and occludin could be important targets to reduce glucose permeability across airway epithelia and suppress bacterial growth. Further
investigation into the mechanisms regulating metformin and \textit{P. aeruginosa} action on airway epithelial tight junctions are now required. Such studies could yield potential alternatives to antibiotics to prevent/suppress hyperglycaemia-induced respiratory infections.
