ABSTRACT

Background
Individual variables and area level variables have been identified as explaining much of the variance in rates of compulsory inpatient treatment.

Aims
Describe rates of voluntary and compulsory psychiatric inpatient treatment in rural and urban settings in England, and to explore the associations with age, ethnicity and deprivation.

Method
Secondary analysis of 2010/11 data from the Mental Health Minimum Dataset.

Results
Areas with higher levels of deprivation had increased rates of inpatient treatment. Areas with high proportions of adults aged 20-39 had some of the highest rates of compulsory inpatient treatment as well as some of the lowest rates of voluntary inpatient treatment. Urban settings had higher rates of compulsory inpatient treatment and ethnic density was associated with compulsory treatment in these areas.

Conclusions
Age structure of the adult population and ethnic density along with higher levels of deprivation can account for the markedly higher rates of compulsory inpatient treatment in urban areas.

Introduction

Mental health services in England have been transformed over the past three decades through the transfer of most care from hospital to the community, where services are available twenty-four hours a day (1, 2, 3, 4). It is therefore surprising that detentions under the Mental Health Act have risen steadily over the same time period. This has reached the point that with the declining number of beds, it is the norm for the majority of inpatients on many NHS psychiatric wards to be detained at any point in time. The reasons for this remain unclear, and are complicated by spatial variation. For example, London has consistently higher rates of compulsory inpatient treatment compared with the rest of the England (5).

Previous studies of psychiatric inpatient treatment have demonstrated higher rates amongst younger adults (6, 7), and those of black and minority ethnicity (8, 9), as well as in urban environments and areas of social deprivation (10, 11, 12, 13). However a multilevel analysis of the rate of compulsory inpatient treatment identified that the majority of the variation in rates occurred at the individual level according to variables such as age and ethnicity (14). Area level deprivation and ethnic density were also factors, but there was no independent effect of London once individual and area level variables had been adjusted for.

Aims

1. To record the rate of psychiatric inpatient treatment (voluntary and compulsory) in England in 2010/11 and describe the variation between rural and urban settings.
2. To investigate whether the variation in these rates of inpatient treatment in rural and urban settings correlated with variations in levels of deprivation, ethnic density and age.
3. We hypothesised that differences in age, ethnic density and deprivation between urban and rural areas would explain differing rates of inpatient treatment.

Methods

Design: This was an ecological study based on secondary analysis of routinely collected national data. The proportion of adults who spent time as a psychiatric inpatient during a one year period was the outcome measure. Information on inpatient treatment was gathered from the Mental Health Minimum Dataset (MHMDS) for the year 2010/11. Data from the MHMDS was linked to corresponding demographic data from the Office for National Statistics (15) enabling rates to be calculated, and other variables to be measured including population age structure, ethnic density and levels of deprivation.

The year studied was 2010/11. The population data used was the mid 2011 population estimates from the Office of National Statistics based on the results of the 2011 census. The 2010 Index of Multiple Deprivation (IMD) median score for each Primary Care Trust was used as a measure of area level deprivation (sourced from http://www.communities.gov.uk/publications/corporate/statistics/indices2010).

The setting was Primary Care Trusts (PCTs, geographically defined areas with mean population size of 350,000; in which primary and secondary care NHS services were organised) in England. These were the smallest areas for which both denominator population data and inpatient data were available. Each PCT was categorised according to its urban or rural location. The Rural/Urban Local Authority classification (https://www.gov.uk/government/statistics/2001-rural-urban-definition-la-classification-and-other-geographies) was modified for the purpose of this study to make seven
Participants had all spent at least one day in a psychiatric hospital during the year 2010/11. Each individual was included only once irrespective of whether they had one or multiple admissions, or had been admitted prior to the year of study. Each participant was allocated to one of two groups according to the level of restriction they were subject to. The first was the voluntary inpatient treatment group consisting of patients who had been in a psychiatric hospital on a voluntary basis or who were detained for an initial assessment only (72 hours duration and in practice usually less than 24 hours).

The compulsory inpatient treatment group consisted of any patient who had been detained in hospital at any point during the year for a longer period of assessment and/or treatment. These patients could also have spent some time in hospital as voluntary patients as well during the year. It included civil detentions from the community (including from A&E, or via the police, or other healthcare settings) and forensic detentions from a court of law or prison. The voluntary and compulsory treatment groups were mutually exclusive.

MHMDS data were available on 143 out of the 152 PCTs in England. Five of these 143 PCTs were excluded as they received the majority of their mental health services from two mental health Trusts that did not return data on compulsory treatment for the year of the study. Thus data is presented on 138 PCTs. The fourteen PCTs that were not included were from different areas of the country including both rural and urban settings.

**Statistical Analysis**

For each PCT the adult population aged (16 years plus), and the percentage aged 20 to 39 years of age were recorded. Rates of psychiatric inpatient treatment (overall, voluntary and compulsory) were calculated per 100,000 of the adult population for each PCT. Average rates were calculated for the whole of England, and for each of the seven rural and urban settings. Spearman’s rank correlations were calculated between average rates of treatment in each of the seven rural/urban settings and the corresponding rates of young adults and ethnic density, and deprivation scores in PCTs in these settings. Variations in the rates of compulsory inpatient treatment and the associations with other variables were then investigated in more detail. All statistical analyses were carried out using SPSS version 19 (16).

**Results**

**Rates of psychiatric inpatient treatment.**

The rate of inpatient psychiatric treatment was 276 (95% CI 262/289) per 100,000 adult population in the year 2010/11. This consisted of a rate of 159 (149/168) per 100,000 of voluntary inpatient treatment, and 117 (107/127) per 100,000 of compulsory inpatient treatment.

**Rates in urban and rural locations**

Urban areas had higher rates of inpatient treatment, and the larger the urban environment the greater the rate of compulsory inpatient treatment, with rates highest in inner London (see Table 1). Rates of voluntary treatment showed a different pattern with the highest rates seen in urban areas outside London, and less overall variation between rural and urban settings. Overall rates of inpatient treatment in inner London were 72% higher when compared with...
the most rural PCTs. Compulsory treatment rates were 184% higher but the rate of voluntary inpatient treatment was only 9% higher in inner London.

Table 1 about here

Age, ethnicity and deprivation also varied between these rural and urban categories. There was a strong or moderate association between levels of deprivation in these urban and rural settings and the rate of inpatient treatment for the corresponding area, both voluntary and compulsory. In addition there were strong associations between the percentage of the adult population aged 20-39 years and ethnic density with the rate of compulsory inpatient treatment, but no association with the rate of voluntary inpatient treatment (see Table 2).

Table 2 about here

**Age and compulsory psychiatric inpatient treatment**

There was a nearly perfect correlation in Table 2 between the proportion of adults that were in their 20s and 30s and the rate of compulsory inpatient treatment. In more urban settings the proportion of adults aged 20-39 years steadily rose as did the rate of compulsory inpatient treatment. The only exception was a slight drop in the proportion of young adults between the large urban and major urban categories. However, there was a similar drop in the rate of compulsory inpatient treatment between these categories. See Figure 1.

Figure 1 about here

**Area level deprivation, ethnic density and compulsory psychiatric inpatient treatment**

The association between area level deprivation and the rate of compulsory inpatient treatment was evident in both rural and urban areas (see Figure 2).

Figure 2 about here

In contrast to deprivation, the association between compulsory inpatient treatment and ethnic density at the PCT level was only evident in urban settings. Figure 3 shows that rural PCTs had lower rates of ethnicity, and no association (or slightly negative association) between rates of compulsory inpatient treatment and ethnicity. Urban PCTs had much higher rates of ethnic density with a positive association between ethnicity and compulsory inpatient treatment.

Figure 3 about here

Regression modelling confirms that age and to a lesser degree ethnicity are key variables in urban environments, rather than rural areas, and the associations are sustained after including interaction terms. The higher rates in urban areas (p=0.063) increase further with a higher proportions of young adults (p=0.051). See Figure 3. The regressions models suggest no significant interactions between urban areas and ethnicity (p=0.119) or between urban areas and deprivation (p=0.812; see Figure 2).
Variation in the rate of inpatient treatment.

Rates of voluntary inpatient treatment were 72.1% (95% CI 44.4/99.8%) higher than rates of compulsory inpatient treatment across all 138 PCTs (voluntary rate 158.7 (149.6/167.7) compulsory rate 117.1 (107.4/126.7) N = 138). PCTs with high rates of young adults tended towards similar rates (voluntary rate 154.4 (138.8/170.1) compulsory rate 154.4 (137.4/171.4) N = 55).

Furthermore in the forty three PCTs with both high proportions of young adults and high levels of ethnic density, average rates of compulsory inpatient treatment were higher (167.2, 147.8/186.7) than rates of voluntary inpatient treatment (148.9, 132.7/165.2), irrespective of area deprivation. More London PCTs (93%) had a high proportion of young adults compared with other urban PCTs (46% and rural PCTs (0%; chi-square = 65.7, df = 2, p < 0.001).

Discussion

This paper reports rates of voluntary and compulsory inpatient psychiatric treatment in seven rural and urban categories across England. The findings indicate that overall rates of inpatient treatment and compulsory rates increase in a stepwise fashion with urban environments: the larger the urban settings the greater the rate. A different pattern was seen for rates of voluntary inpatient treatment.

Our findings indicate that part of the explanation of the differences in rates between rural and urban areas is the age profile in these differing settings. Age, particularly young adulthood came out as a strong explanatory variable in our multilevel analysis of the variation in rates of compulsory psychiatric admission (14). In the fully adjusted multilevel model the odds ratio for compulsory admission was 1.92 (1.82/2.02) in those aged 18-35, and 1.79 (1.68/1.89) in those aged 36-65 compared with those aged under 18.

In this current paper we put forward evidence for an association between age and urban environments, and to a lesser extent ethnicity and urban environments. Furthermore we also demonstrate why London was not identified as an explanatory variable in the previous multilevel analysis of compulsory admission rates: namely the age and ethnic profile of London. PCTs with above average proportions of adults in their 20s and 30s had rates of compulsory inpatient treatment that were 67% higher and these PCTs were highly clustered in London. This important finding has implications for future research and service provision. Any future comparisons of the use of compulsory treatment by mental health services will need to control for the age of the local population.

It is well established that rural areas in particular have low proportions of young adults (17). In addition areas with high proportion of young adults had low rates of voluntary inpatient treatment. London had particularly high proportions of young adults, and in contrast to other areas had higher rates of compulsory treatment than voluntary treatment. There may be a number of possible explanations for why rates of voluntary admission were not higher in the most urban environments: pathways into care in urban setting may be more likely to result in involuntary treatment; fewer older adults who are less likely to be detained live in these areas; the high rate of involuntary admission may limit the capacity for voluntary admission. We found evidence for an age/urban interaction and higher rates of compulsory treatment.
Deprivation was associated with rates of inpatient psychiatric treatment – both voluntary and compulsory. In contrast ethnicity was only associated with rates of compulsory inpatient treatment. We found some weak evidence for an ethnicity/urban interaction and higher rates of compulsory treatment. It was also only in large and major urban areas, and particularly in London, that higher than average rates of deprivation, young adults and ethnic density were found together, and these areas had the highest rates of compulsory inpatient treatment.

As seen in other conditions (18) there may be underlying contextual factors in these urban areas that invoke interactions between individuals and multiple vulnerabilities, leading to poorer health indices in general, and higher rates of compulsory treatment. Furthermore the contextual factors in rural areas are likely to be different from urban areas. Our findings suggest that for a meaningful comparison to be made of rates of compulsory treatment between different mental health services, controlling for the setting in which each of the services operates will be vital.

Limitations of the study include that it is a secondary analysis of routinely collected data. In addition it is an ecological study and explores association at the population and group level rather than at the individual level. So associations can only be used to inform service delivery, and not individual level interventions.

The age profile of each ethnic group in England varies considerably with the most minority ethnic groups being much younger than the majority white British population (19). Furthermore many ethnic groups are highly clustered in major urban areas including London. Black and Asians groups in particular have been identified as being at greater risk of compulsory inpatient treatment. These groups make up just 1.3% of the rural population compared with 12.6% of the urban population, and 20.7% of the population in major conurbations (20). Intriguingly there is a suggestion in our results that rural areas with relatively high levels of ethnicity had some of the lowest rates of compulsory admission. This suggests that part of the explanation for the over-representation of ethnic groups amongst compulsory psychiatric inpatients may be that these groups tend to be younger and highly concentrated in urban areas. It may also explain why some of the ethnic groups with the lowest rates of compulsory inpatient treatment are more evenly spread through the country.

The population of England has risen steadily in the last 30 years and continues to grow. This growth has been largely confined to urban environments, and this may be part of the explanation for the increasing rates of compulsory admission that have taken place during this time period (20). There is a need to understand the distribution of compulsory admission in other countries with different jurisdictions to see if they show a similar pattern of concentration in large and major urban areas.
